

# Linguistics 384: Language and Computers

## Topic 4: Writer's aids (Spelling and Grammar Correction)

Scott Martin\*

Dept. of Linguistics, OSU  
Winter 2008

---

\* The course was created by Chris Brew, Markus Dickinson and Detmar Meurers.

### Introduction

### Error causes

- Keyboard mistypings
- Phonetic errors
- Knowledge problems

### Difficult issues

- Tokenization
- Inflection
- Productivity

### Non-word error detection

- Dictionaries
- N-gram analysis

### Isolated-word error correction

- Rule-based methods
- Similarity key techniques
- Probabilistic methods
- Minimum edit distance

### Grammar correction

- Syntax
- Computing with Syntax
- Grammar correction rules

### Caveat emptor

# Who cares about spelling?

*Aoccdrnig to a rscheearch at Cmabrigde  
Uinervtisy, it deosn't mttar in waht oredr the ltteers  
in a wrod are, the olny iprmoetnt tihng is taht the  
frist and lsat ltteer be at the rghit pclae. The rset  
can be a toatl mses and you can sitll raed it wouthit  
porbelm. Tihs is bcuseae the huamn mnid deos not  
raed ervey lteter by istlef, but the wrod as a wlohe.*

## Introduction

### Error causes

- Keyboard mistypings
- Phonetic errors
- Knowledge problems

### Difficult issues

- Tokenization
- Inflection
- Productivity

### Non-word error detection

- Dictionaries
- N-gram analysis

### Isolated-word error correction

- Rule-based methods
- Similarity key techniques
- Probabilistic methods
- Minimum edit distance

### Grammar correction

- Syntax
- Computing with Syntax
- Grammar correction rules

### Caveat emptor

# Who cares about spelling?

- Probabilistic methods
- Minimum edit distance

### Grammar correction

- Syntax
- Computing with Syntax
- Grammar correction rules

### Caveat emptor

# Why people care about spelling

- ▶ Misspellings can cause misunderstandings and real-life problems:
  - ▶ For example:
    - ▶ Did you see her god yesterday? It's a big golden retriever.

## Introduction

### Error causes

Keyboard mistypings  
Phonetic errors  
Knowledge problems

### Difficult issues

Tokenization  
Inflection  
Productivity

### Non-word error detection

Dictionaries  
N-gram analysis

### Isolated-word error correction

Rule-based methods  
Similarity key techniques  
Probabilistic methods  
Minimum edit distance

### Grammar correction

Syntax  
Computing with Syntax  
Grammar correction rules

### Caveat emptor

# Why people care about spelling

- ▶ Misspellings can cause misunderstandings and real-life problems:
  - ▶ For example:
    - ▶ Did you see her god yesterday? It's a big golden retriever.
    - ▶ This will be a fee [free] concert.

## Introduction

### Error causes

Keyboard mistypings  
Phonetic errors  
Knowledge problems

### Difficult issues

Tokenization  
Inflection  
Productivity

### Non-word error detection

Dictionaries  
N-gram analysis

### Isolated-word error correction

Rule-based methods  
Similarity key techniques  
Probabilistic methods  
Minimum edit distance

### Grammar correction

Syntax  
Computing with Syntax  
Grammar correction rules

### Caveat emptor

# Why people care about spelling

- ▶ Misspellings can cause misunderstandings and real-life problems:
  - ▶ For example:
    - ▶ Did you see her god yesterday? It's a big golden retriever.
    - ▶ This will be a fee [free] concert.
  - ▶ 1991 Bell Atlantic & Pacific Bell telephone network outages were partly caused by a typographical error: A 6 in a line of computer code was supposed to be a *D*. "That one error caused the equipment and software to fail under an avalanche of computer-generated messages." (Wall Street Journal, Nov. 25, 1991)

## Introduction

### Error causes

Keyboard mistypings  
Phonetic errors  
Knowledge problems

### Difficult issues

Tokenization  
Inflection  
Productivity

### Non-word error detection

### Isolated-word error correction

Rule-based methods  
Similarity key techniques  
Probabilistic methods  
Minimum edit distance

### Grammar correction

Syntax  
Computing with Syntax  
Grammar correction rules

### Caveat emptor

# Why people care about spelling (cont.)

- ▶ Standard spelling makes it easy to organize words and text:
  - ▶ e.g., Without standard spelling, how would you look up things in a lexicon or thesaurus?
  - ▶ e.g., Optical character recognition software can use knowledge about standard spelling to recognize scanned words even for hardly legible input.
- ▶ Standard spelling makes it possible to provide a single text, which is accessible to a wide range of readers (different backgrounds, speaking different dialects, etc.).
- ▶ Using standard spelling is associated with being well-educated, i.e., is used to make a good impression in social interaction.

## Introduction

### Error causes

Keyboard mistypings  
Phonetic errors  
Knowledge problems

### Difficult issues

Tokenization  
Inflection  
Productivity

### Non-word error detection

### Caveat emptor

# Tokenization

Intuitively a “word” is simply whatever is between two spaces, but this is not always so clear.

- ▶ contractions = two words combined into one
  - ▶ e.g., *can't, he's, John's [car]* (vs. *his car*)
- ▶ multi-token words = (arguably) a single word with a space in it
  - ▶ e.g., *New York, in spite of, deja vu*
- ▶ hyphens (note: can be ambiguous if a hyphen ends a line)
  - ▶ Some are always a single word: *e-mail, co-operate*
  - ▶ Others are two words combined into one:  
*Columbus-based, sound-change*

#### Caveat emptor

## Intuition:

- ▶ Have a complete list of words and check the input words against this list.
- ▶ If it's not in the dictionary, it's not a word.

## Two aspects:

- ▶ **Dictionary construction** = build the dictionary (what do you put in it?)
- ▶ **Dictionary lookup** = lookup a potential word in the dictionary (how do you do this quickly?)

Grammar correction rules

### Caveat emptor

- ▶ word length effects: most misspellings are within two characters in length of original
  - When searching for the correct spelling, we do not usually need to look at words with greater length differences.
- ▶ first-position error effects: the first letter of a word is rarely erroneous
  - When searching for the correct spelling, the process is sped up by being able to look only at words with the same first letter.

# Similarity key techniques

- ▶ Problem: How can we find a list of possible corrections?
- ▶ Solution: Store words in different boxes in a way that puts the similar words together.
- ▶ Example:
  1. Start by storing words by their first letter (first letter effect),
    - ▶ e.g., *punc* starts with the code P.

### Caveat emptor

# Confusion probabilities

- ▶ For the various reasons discussed above (keyboard layout, phonetic similarity, etc.) people type other letters than the ones they intended.
- ▶ It is impossible to fully investigate all possible error causes and how they interact, but we can learn from watching how often people make errors and where.
- ▶ One way of doing so is to build a **confusion matrix** = a table indicating how often one letter is mistyped for another

		correct				
		...	r	s	t	...
typed	⋮					
	r		n/a	12	22	
	s		14	n/a	15	
	t		11	37	n/a	
	⋮					

(cf. Kernighan et al 1999)

# Computing edit distances

## Figuring out the worst case

- ▶ To be able to compute the edit distance of two words at all, we need to ensure there is a finite number of steps.
- ▶ This can be accomplished by
  - ▶ requiring that letters cannot be changed back and forth a potentially infinite number of times, i.e., we
  - ▶ limit the number of changes to the size of the material we are presented with, the two words.
- ▶ Idea: Never deal with a character in either word more than once.
- ▶ Result:
  - ▶ In the worst case, we delete each character in the first word and then insert each character of the second word.
  - ▶ The worst case edit distance for two words is  $length(word1) + length(word2)$

# Computing edit distances

Using a graph to map out the options

- ▶ To calculate minimum edit distance, we set up a **directed, acyclic graph**, a set of nodes (circles) and arcs (arrows).
- ▶ Horizontal arcs correspond to deletions, vertical arcs correspond to insertions, and diagonal arcs correspond to substitutions (and a letter can be “substituted” for itself).

## Introduction

# Computing edit distances

## An example graph

- ▶ Say, the user types in *plog*.
- ▶ We want to calculate how far away *peg* is (one of the possible corrections). In other words, we want to calculate the minimum edit distance (or minimum edit cost) from *plog* to *peg*.
- ▶ As the first step, we draw the following directed graph:

### Introduction

#### Caveat emptor

# Computing edit distances

## Adding numbers to the example graph

- ▶ The graph is **acyclic** = for any given node, it is impossible to return to that node by following the arcs.
- ▶ We can add identifiers to the states, which allows us to define a **topological order**:

#### Caveat emptor

# Computing edit distances

## Adding costs to the arcs of the example graph

- ▶ We need to add the costs involved to the arcs.
- ▶ In the simplest case, the cost of deletion, insertion, and substitution is 1 each (and substitution with the same character is free).

- ▶ Instead of assuming the same cost for all operations, in reality one will use different costs, e.g., for the first character or based on the confusion probability.

# Computing edit distances

How to compute the path with the least cost

We want to find the path from the start (1) to the end (20) with the least cost.

- ▶ The simple but dumb way of doing it:
  - ▶ Follow every path from start (1) to finish (20) and see how many changes we have to make.
  - ▶ But this is very inefficient! There are many different paths to check.

# Computing edit distances

The smart way to compute the least cost

- ▶ The smart way to compute the least cost uses **dynamic programming** = a program designed to make use of results computed earlier
  - ▶ We follow the topological ordering.
  - ▶ As we go in order, we calculate the least cost for that node:
    - ▶ We add the cost of an arc to the cost of reaching the node this arc originates from.
    - ▶ We take the minimum of the costs calculated for all arcs pointing to a node and store it for that node.
  - ▶ The key point is that we are storing partial results along the way, instead of recalculating everything, every time we compute a new path.

    - ▶ e.g., *They are leaving in about fifteen **minuets** to go to her house.*
- ⇒ *minuets* and *minutes* are both plural nouns, but only one makes sense here

There are many different ways in which grammar correctors work, two of which we'll focus on:

- ▶ Bigram model (bigrams of words)
- ▶ Rule-based model

# Properties of Phrase Structure Rules

- ▶ **generative** = a schematic strategy that describes a set of sentences completely.
- ▶ potentially **(structurally) ambiguous** = have more than one analysis

(14) We need more intelligent leaders.

(15) Paraphrases:

- a. We need leaders who are more intelligent.
- b. Intelligent leaders? We need more of them!

- ▶ **hierarchical** = categories have internal structure; they aren't just linearly ordered.
- ▶ **recursive** = property allowing for a rule to be reapplied (within its hierarchical structure).

### Caveat emptor

A **context-free grammar** (CFG) is essentially a collection of phrase structure rules.

- ▶ It specifies that each rule must have:
  - ▶ a left-hand side (LHS): a single **non-terminal** element = (phrasal and lexical) categories
  - ▶ a right-hand side (RHS): a mixture of non-terminal and terminal elements  
**terminal** elements = actual words
- ▶ A CFG tries to capture a natural language completely.

Why “context-free”? Because these rules make no reference to any context surrounding them. i.e. you can't say “PP → P NP” *when* there is a verb phrase (VP) to the left.

### Caveat emptor

**Pushdown automaton** = the computational implementation of a context-free grammar.

It uses a **stack** (its memory device) and has two operations:

- ▶ **push** = put an element onto the top of a stack.
- ▶ **pop** = take the topmost element from the stack.

This has the property of being **Last In First Out (LIFO)**.

So, when you have a rule like “PP → P NP”, you push NP onto the stack and then push P onto it. If you find a preposition (e.g., *on*), you pop P off of the stack and now you know that the next thing you need is an NP.

# A Poem on the Dangers of Spell Checkers

Michael Livingston

*Eye halve a spelling chequer  
It came with my pea sea.  
It plainly marques four my revue  
Miss steaks eye kin knot sea.  
Eye strike a key and type a word  
And weight four it two say  
Weather eye am wrong oar write  
It shows me strait a weigh.  
As soon as a mist ache is maid  
It nose bee fore two long  
And eye can put the error rite  
Its rare lea ever wrong.  
Eye have run this poem threw it  
I am shore your pleased two no  
Its letter perfect awl the weigh  
My chequer tolled me sew.*
